Pull request:		
Description Cloned from https://bugzilla.redhat.com/show_bug.cgi?id=1258327 Description of problem: In very big environments where over 800 Subnets and hundreds of Domains exist it is a very big overhead to be forced to configure Domains & Subnets in the Satellite Server when an IP Address Management system (IPAM) is already in place having all those information. Version-Release number of selected component (if applicable): 6.1.1 Actual results: User is forced to configure Domains & Subnets to be able to use Satellite Provisioning Expected results: Add the possibility to specify Domain & Network information freely not having to create/manage hundreds of Domains & Subnets on host creation level. This would ease the integration of Satellite 6 to other provisioning frameworks where Satellite is only one of several tools being used to provisioning systems.
