Description		
<p>Good morning together,</p> <p>i installed january this year a fresh 1.14.1 Foreman with Puppet Server on CentOS with a connected VMWare 5.5 vSphere server to deploy hosts on VMWare over foreman-vmware plugin. It worked fine.</p> <p>Now we create a new VMWare 6.5 vSphere Server and i want connect this vSphere Server with Foreman. When i creating a new Resource from the type VMWare, entering the login data to the VMWare 6.5 server and click "load datacenter" it said "connection successfully" and the hash is saved, but no datacenter are shown in the listbox to chooese. With VMWare 5.5, my Datacenters are loaded fine.</p> <p>Is the foreman-vmware plugin compatible with VMWare 6.5 ? Can i do something to check what cause this problem? Did i have to update Foreman? I found not really a release note or compatibly overview of the foreman-vmware plugin, so i dont know where to start to fix this problem. I dont know if its my problem, or a critical bug in the software.</p> <p>Iam thankful for any help</p> <p>Best Regards</p> <p>Quin</p>

- Priority changed from High to Normal

Good morning,

the "error" caused by the local Administrator login-data from vSphere. It seems the local login does not work without extensions (FQDN\Administrator or Administrator@fqdn). With my local domain user name and password the datacenter are succesfully loaded. So i can confirm vSphere 6.5 works, but sth. with the login-data error handling does not work correct.

Regards
